HACKTOBERFEST @ H-FARM · CHALLENGE BRIEF

H-OS

The AI Operating System of the campus.

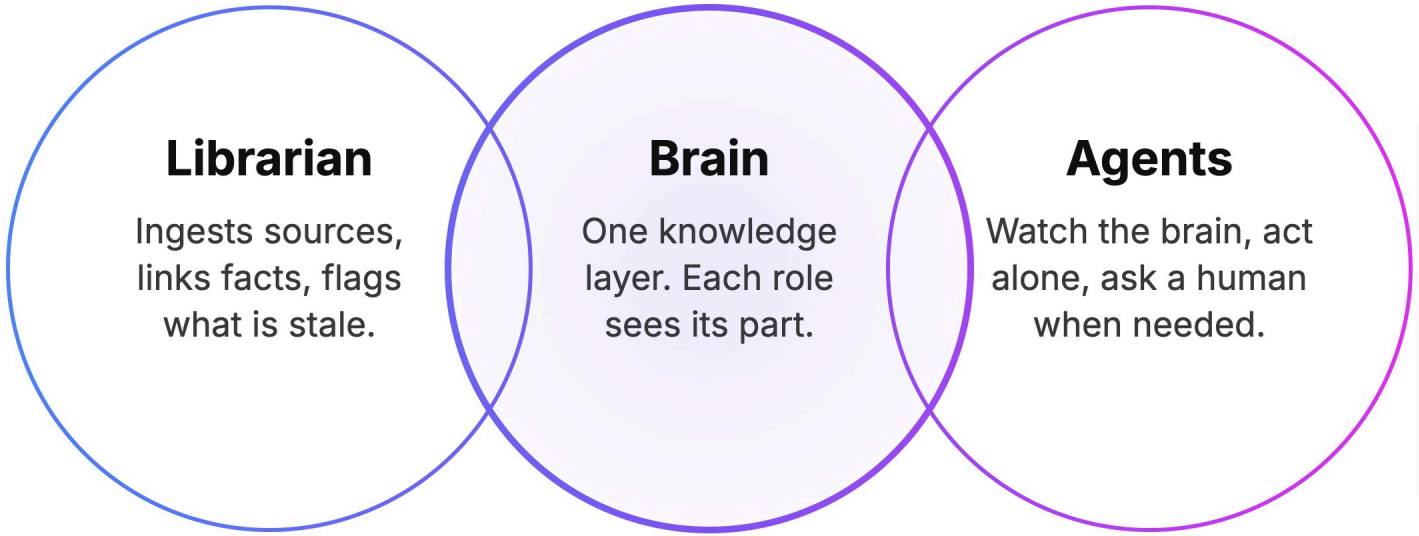

Build an open source **company brain** for H-FARM, a **librarian** that keeps it alive, and **proactive agents** that act on their own and ask a human only when it matters.

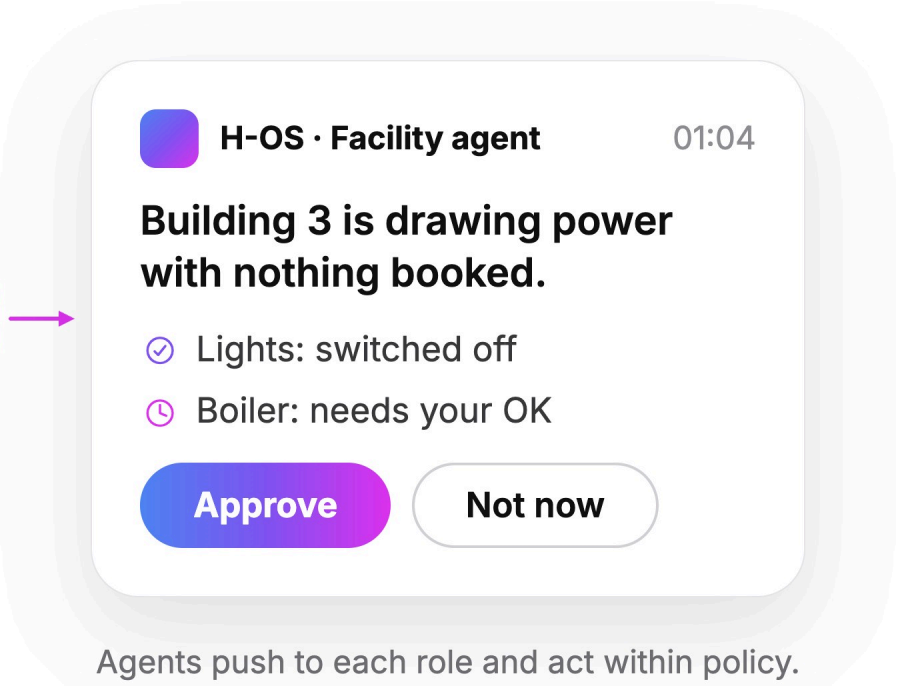

THE NORTH STAR

Can we build an organization that understands itself?

Three parts. One loop.

How would you architect the first working version of H-OS?

Agents push to each role and act within policy.

Think about: the knowledge layer and the organizational graph, who sees what as roles change, how LLMs, rules and agents work together, interfaces for people and for agents (MCP), open-weight models on hardware we own.

The pieces are already open source.

H-OS mixes a company brain, proactive agents and access control by role. Start from these.

Agents Access

Company brain
+ proactive agents
+ access control
= H-OS.

Pick a workflow. Ship the loop.

The life of a campus event

From contract to cash

Or propose your own. Bring your own data: a small synthetic dataset, or public sources such as the events on h-farm.com.

Guardrails. Synthetic or public data only, no access to H-FARM systems, actions on mocks. A human approves anything that leaves the organization, spends money, writes to a system of record or changes access. No invoices issued. Nothing that monitors or scores people.

What you ship

01 An open source repo, MIT or Apache-2.0

02 The Brain and the Librarian that keeps it alive

03 One agent that acts on its own and asks permission on a concrete case

04 A working loop with three roles, every answer citing its sources

05 A one-page architecture and a live demo

One workflow done well beats eight layers half built.
